

AirSense AI

Mobile App Wireframing & Design Thinking — Internship Submission

Project type: Low-fidelity mobile UX prototype

Purpose: Help urban users quickly understand air quality, forecast changes, and personalized actions.

Prototype scope: onboarding/location, current AQI, forecast, map, alerts, and health profile.

1. Problem Statement

Air-quality information can be difficult to interpret quickly. Users need a simple mobile experience that turns AQI and pollutant data into understandable status, forecast context, alerts, and practical next steps.

2. Target Users

Primary users are students and young urban residents who regularly make outdoor decisions and want quick, understandable air-quality information.

3. Rapid User Research

Research method: a short questionnaire/interview with 5–10 target users. The included questionnaire is ready to use. The initial prototype synthesis below is an assumption-based starting point and should be validated with real responses before final submission.

Area	Initial prototype assumption
Current behavior	Users check weather/AQI before going outdoors.
Main difficulty	AQI numbers and pollutant values are not always easy to interpret.
Desired information	Current AQI, forecast, pollutant breakdown, and actionable advice.
Alerts	Users want alerts when conditions become meaningfully worse.
Personalization	A basic health/sensitivity profile can make recommendations more relevant.

4. User Persona

Riya Sharma, 20, college student

Goals: know whether outdoor activity is safe, understand AQI quickly, receive timely alerts.

Pain points: AQI values feel abstract, information is scattered, and long reports are inconvenient.

Needs: clear status, forecast, personalized recommendations, and simple notifications.

5. User Flow

Open app → confirm location → view current AQI → view details → check forecast → set/manage alerts → maintain health profile → receive alert → follow recommendation → return to Home.

6. Low-Fidelity Wireframes

Six mobile screens were designed as intentionally low-fidelity wireframes. The focus is information hierarchy, navigation, and task completion—not final visual styling.

Screens: Onboarding/Location • Home/Current AQI • Forecast • Air Quality Map • Alerts • Health Profile

The SVG wireframe board included with this submission can be imported into Figma and used as the starting point for the prototype.

7. Design Thinking Process

Stage	What was done
Empathize	Defined target users and prepared a short research questionnaire.
Define	Framed the problem as fast, understandable air-quality decision support.
Ideate	Prioritized current AQI, details, forecast, map, alerts, and personalization.
Prototype	Created six low-fidelity mobile screens and a core user flow.
Test	Next step: test the wireframes with 5–10 users and iterate based on observed issues.

8. Expected Outcome

The prototype demonstrates an early-stage mobile information architecture and user journey for AirSense AI. It provides a clear foundation for later high-fidelity UI design, usability testing, and implementation.
